A. Predictors: what shapes intention?

The dissertation distinguishes **destination image** from other predictors of behavioural intention.

eCFTD element	Example passage	Interpretation
Cognitive destination image	"A lakeside trail, a small-group guided walk, and a café serving local food."	Beliefs and knowledge about destination attributes
Affective destination image	"The destination look[s] peaceful, and I feel excited about visiting."	Feelings associated with the destination
Attitude towards the behaviour	"I prefer activities that support local businesses and respect nature."	Evaluation of participating in this type of activity
Subjective norms	"My friends also encouraged me to choose this destination."	Perceived social encouragement
Perceived behavioural control (PBC)	"Booking look[s] straightforward, and I think I could manage the walk."	Perceived ease or difficulty of performing the behaviour

Important distinction: In eCFTD, destination image contains **cognitive perceptions and affective responses**, not intentions. "The destination seems peaceful" describes image; "I plan to visit" expresses intention.

The dissertation identifies destination marketing, user-generated content, and AI-generated content as possible sources shaping image. In this example, the website represents destination communication, and previous reviews represent user-generated content.

B. Behavioural intentions: what does the visitor intend to do?

Intention category	Example
Exploratory intention	"I plan to visit next month."
Transactional intention	"I plan to … book the guided walk."
Virtual intention	"I plan to … try the virtual preview beforehand."
Social intention	"I would like to share it with my friends."
Revisit intention	"I intend to return in winter."

These are intentions, not evidence that the corresponding actions occurred.

C. Volitional mediators: how does intention become action?

The article's detailed definitions identify **action planning and self-efficacy as mediators**.

Mediator	Example	Its proposed role
Action planning	"I checked the bus timetable, chose a date, and arranged to travel with a friend."	Makes the intended activity concrete and executable

Self-efficacy	"I felt confident that I could participate."	Supports confidence in carrying out the intended activity

The alternative bus route also illustrates a practical response to a possible obstacle. **Based on the framework, this suggests a planning process supporting action**, although the supplied excerpts do not establish it as a separate named component.

PBC and self-efficacy overlap conceptually but should not simply be merged. In this example, PBC concerns the perceived overall feasibility of visiting; self-efficacy concerns confidence in completing the walk. This is an illustrative distinction, not a claim that review language alone reliably separates them.

D. Moderators: under what conditions does intention become action?

Moderator or contextual condition	Example	Interpretation
Intention stability	"I still wanted to go several weeks after first discovering the destination."	The intention persists over time
Temporal distance	"I plan to visit next month."	Time separates intention formation from possible action
Accessibility	"The evening bus service was limited."	Access conditions constrain participation
Practical control or resource constraints	"I need to check my work schedule and winter transport options."	Circumstances may prevent an intended return

A terminology correction is needed here: the dissertation's detailed Article III definitions classify **intention stability as a moderator**, although some summary passages group it with volitional mediators. For a precise presentation, distinguish **action planning and self-efficacy as mediators** from **intention stability and temporal distance as moderators**.

E. Observable actions: what happened?

Action category	Example
Physical engagement	Joining the walk and completing the shorter route
Economic transaction	Buying tour tickets and purchasing lunch
Social action	Posting photographs, writing a review, and recommending the destination
Virtual behaviour	Participation in the virtual preview—**only if its completion is documented**

Table 2. Definition of Key Concepts

Concept	Definition
Tourism knowledge	The structures, processes, and outcomes through which the phenomenon of tourism is understood. It is treated as socially constructed and multi-layered rather than directly representational (Tribe & Liburd, 2016). This dissertation specifies tourism knowledge as that produced from digital data under conditions of recognized platform mediation, methodologically transparent analysis, and conceptually coherent interpretation.
Algorithmic selectivity	The sixth filter in tourism knowledge production proposed in this dissertation. It refers to the processes through which digital platforms filter, rank, suppress, and amplify content according to proprietary algorithms before researchers access their data. It precedes and conditions all five selectivities identified by Tribe and Liburd (2016). It is a structural condition of data availability, not a sampling error.
Cognitive-affective-conative model	A tripartite framework originating in psychology and widely adopted in tourism research. It proposes that attitudes and images consist of cognitive components based on beliefs, affective components based on emotions, and conative components related to intentions or actions (Gartner, 1994). This dissertation critically examines the conative component for internal inconsistency (Josiassen et al., 2016).
Extended conative framework for tourism destinations	A conceptual model proposed in Article III. It separates behavioral intentions from observable actions, removes conative elements from the destination image constructed to cut circular reasoning, and integrates volitional factors such as self-efficacy, action planning, and intention stability. It is designed for potential applications across physical, virtual, and synthetic destinations.
Contribution of theory / Contribution to theory	A dual-classification framework for assessing the nature of theoretical engagement in empirical research (Venkatesh, 2025; Whetten, 2009). Contribution of theory (COT) refers to the application of an existing theoretical framework to a new empirical context without modifying, extending, or challenging the framework itself. The theory is used as a lens but is not itself advanced. Contribution to theory (CTT) refers to research that generates new theoretical elements, modifies existing constructs, identifies previously unrecognized mechanisms, or produces falsifiable propositions that extend the boundaries of what a theory can explain.
Thick Big Data	An approach that combines computational scalability with the contextual nuance of small-scale qualitative research. It bridges the divide between computational scale and interpretive depth in digital data analysis (Bornakke & Due, 2018; Shu & Ye, 2023).
Psycholinguistic transformation	The process of converting unstructured text into semantically structured representations through natural language processing. The transformation is grounded in the “Big Three” parts of speech found across languages: adjectives, verbs, and nouns (Pinker & Jackendoff, 2009).

Q31. What is the difference between intention, volition, and action?

Suggested answer:

> Intention concerns what someone plans or wants to do. Volition concerns the processes through which that intention is carried forward, such as planning and confidence in execution. Action concerns what is actually performed.
>
> A visitor may intend to return, make practical arrangements, and then return—or encounter a barrier and not return. These are distinct elements of explanation.

Q33. What counts as an observable action in review data?

Suggested answer:

> We must distinguish an observed digital action, a reported action, and independently corroborated behaviour.
>
> The existence of a published review shows review-posting activity. Its statement "I returned" reports another action but does not independently verify it.
>
> A transaction record provides stronger evidence of a purchase, although it does not necessarily establish attendance or satisfaction.

Q41. How has your own position shaped this dissertation?

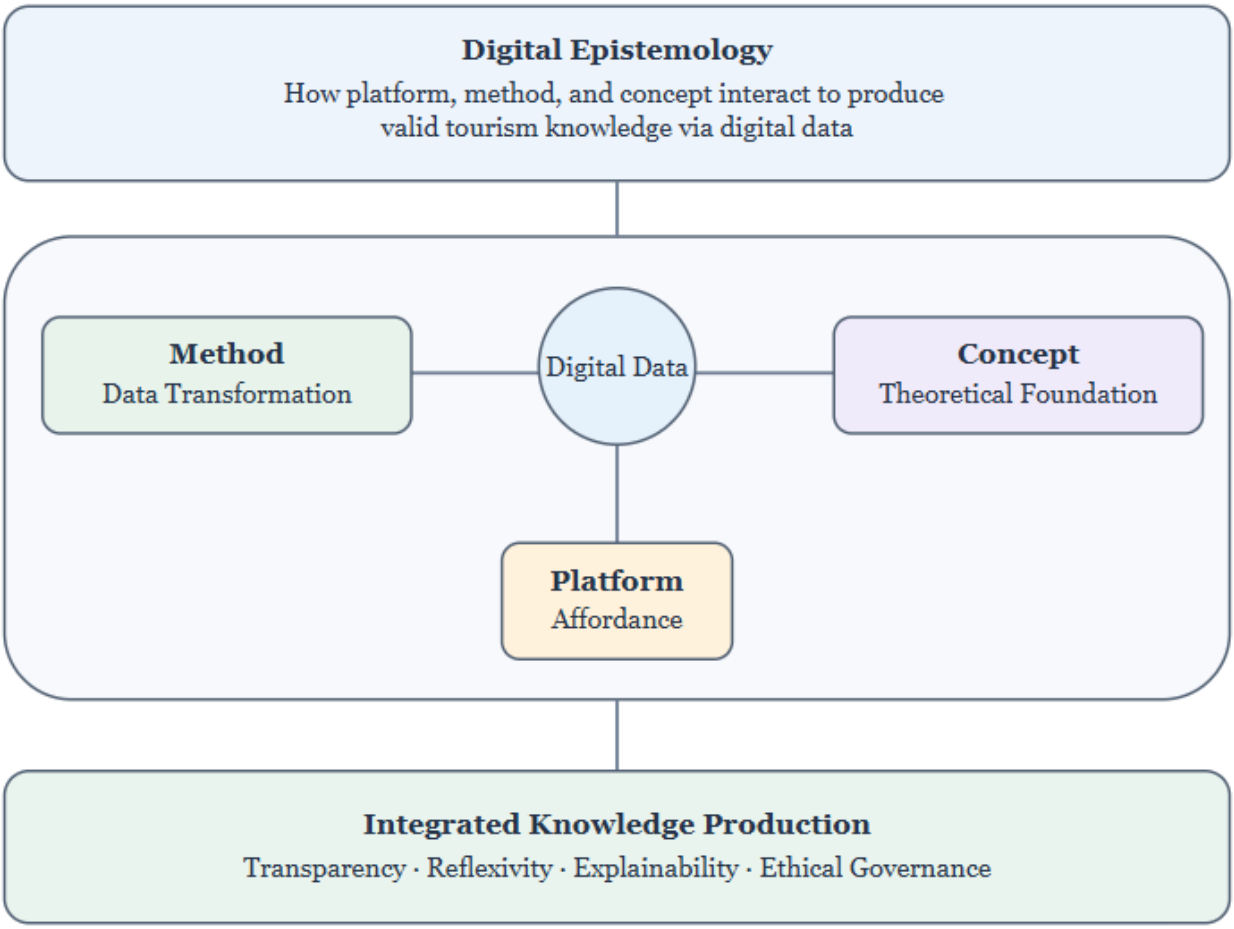

Suggested answer:

> My tourism-business training, Western academic setting, English-language publication environment, and access to Finnish research projects influenced the questions and methods I selected.
>
> The dissertation explicitly applies its selectivity argument to itself. Other researchers might prioritize participatory methods, different platforms, or other knowledge traditions.
>
> Reflexivity contextualizes the contribution; it does not exempt it from criticism.

Q42. What can a tourism organization do with your results now?

Suggested answer:

> The most immediately defensible application is the three-step diagnostic: examine the data source, inspect the analytical pathway, and assess the concepts used in interpretation.
>
> Organizations need not adopt KPTopic to use that diagnostic. They can also avoid combining stated revisit intentions and
